No Time to Kill for Barge Operation
Nugent Sand Eliminates Downtime with Force Control Oil Shear Brakes

The scene is serene and picturesque. Sunshine reflects off the light chop of the Ohio River, as a barge winds its way into view. While those driving along Louisville’s River Road may be inclined to reach for a camera to capture this idyllic scene, the mood at Nugent Sand Company is anything but tranquil. Workers here have a goal to send the deck barge—emptied of its contents—along its way quickly so they can be ready for the next arrival which will be along shortly. There is no downtime for either men or machine. That is why the facility switched from traditional dry friction brakes to MagnaShear Oil Shear Brakes from Force Control Industries.

All day long, deck barges loaded with 1,100-1,200 tons of aggregate arrive at Nugent Sand Company’s Louisville facility. When the barge approaches the unloading zone, lines from a WW Patterson winch are attached fore and aft. Powered by a 7½ hp Baldor motor, each line is tightened or loosened to “jog” the barge into place—and position the vessel within reach of the dockside excavator’s 5-yard clamshell bucket. To keep the excavator arm swing to a minimum (and thus speeding the process), each motor and brake is subjected to numerous start/stop cycles for each barge unloaded. However, the motor is only as good as the brakes that stop it—and friction pads on their dry friction brakes were failing all too often—every six weeks or so.

When that occurred, crew members had to replace the pad—a process which required at least an hour and cost $300 in parts each time. In addition to the raw cost of repair parts, a towboat was launched to replace the winch operation with an alternate means of “jogging” the barge into position. Although the time required to position the barges with the boat is comparable to positioning with the winch, the cost is much greater. “When we have a boat in the water we have an hourly fuel burn of about $30/hour” said Engineering Director Damon Hughes, “plus maintenance and ship-side repairs. The operating cost of the dry brake is just too high.”

Additionally, there are other “soft production deficiencies” when using a towboat rather than the winches. Ideally, the towboat will move other barges into position so that when the vessel currently being unloaded is emptied it can be efficiently sent downstream and replaced with another full barge. However, devoting all of their time to the barge being unloaded prevents the crew from pre-positioning other barges which slows the process in general. Also, the pilot and deckhand are prevented from doing any of their normal maintenance and cleaning when they are engaged in constantly repositioning the barge being unloaded.

In an industry with razor sharp margins any unintended cost or cost increase can mean the difference between black ink and red. So Hughes began researching alternatives. Luckily, the solution was right under their nose—literally. About six years ago, when seeking an alternative to high brake failures and maintenance requirements, they replaced a Stearns dry friction brake on one of the Baldor motors with a MagnaShear MS6. “We’ve had that brake for years, and have not had to do anything to it,” recalls Hughes. “Other than changing the oil annually, there are no adjustments, no repairs and the operating costs are dramatically lower.”

How Oil Shear Technology Works
Normal dry brakes employ a sacrificial surface—a disc or pad—to engage the load. Having no good way to remove the heat caused from engagement between the disk and plate, this material
